Fig 1a from P
Stuyfzand ES

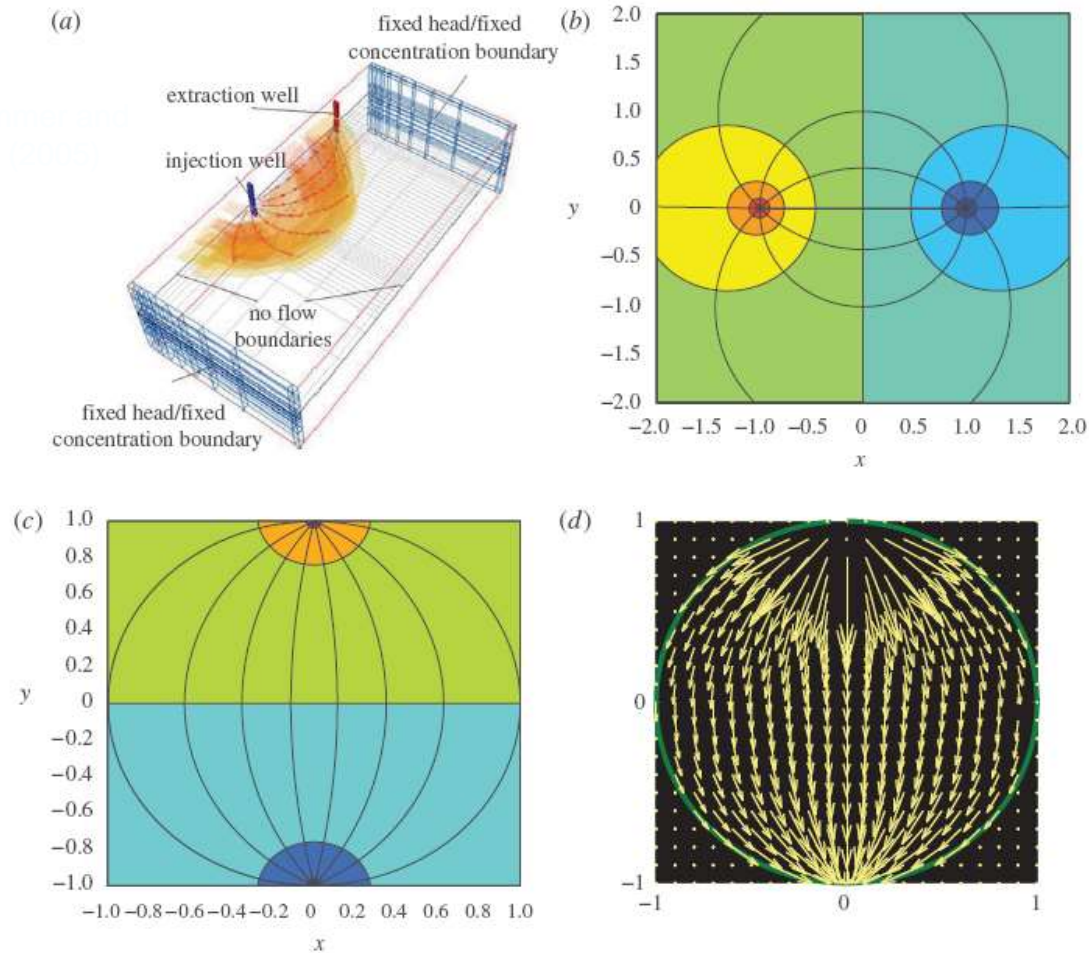

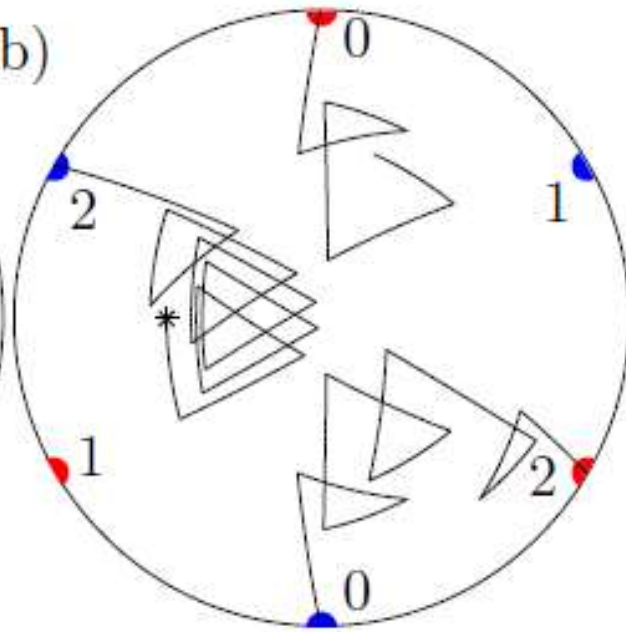

Figure 1. Levels of abstraction leading from the field to a laboratory experiment: (a) flow from an injection well to an extraction well; (b) source and sink on the real axis of the complex plane. Contours of the velocity potential are in colour and lines of the orthogonal streamfunction are shown; (c) the flow of (b) mapped to the disc of unit radius; (d) vector velocity field of (c).

(a)

(b)

The 2D RPM Flow

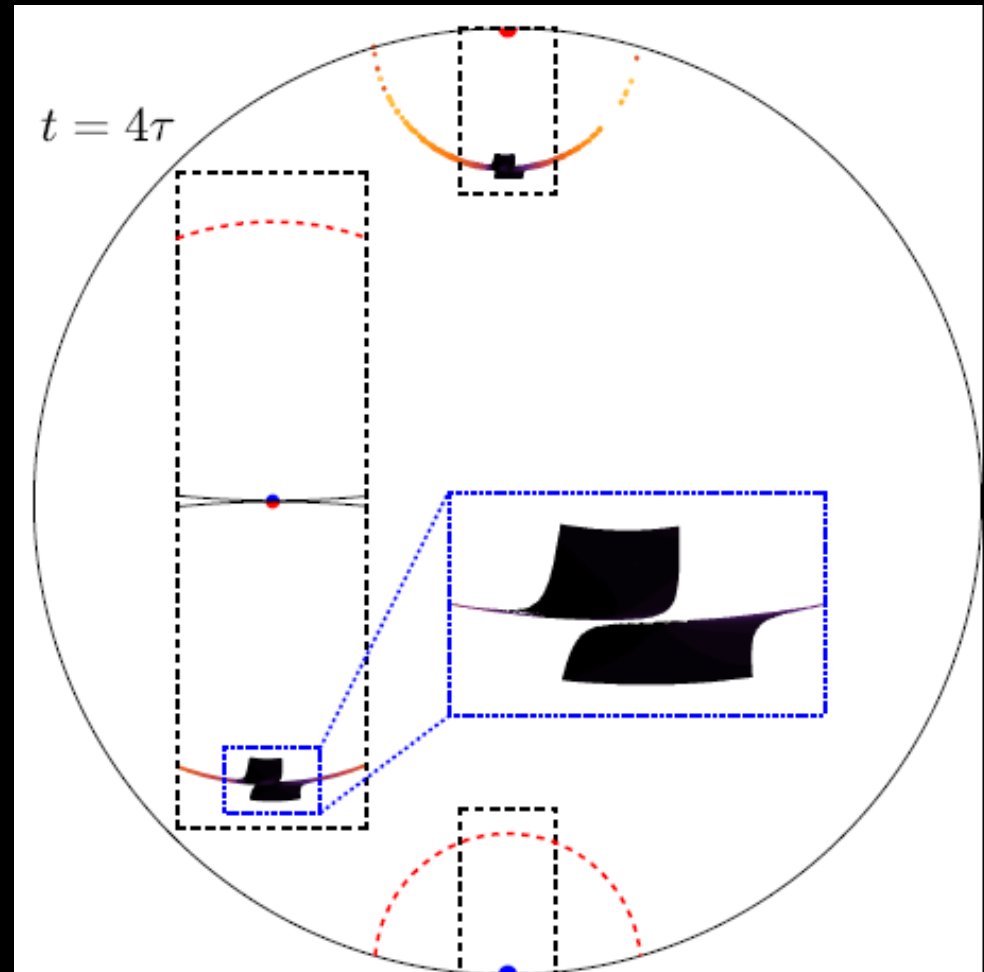

τ = switching period
 Θ = rotation angle

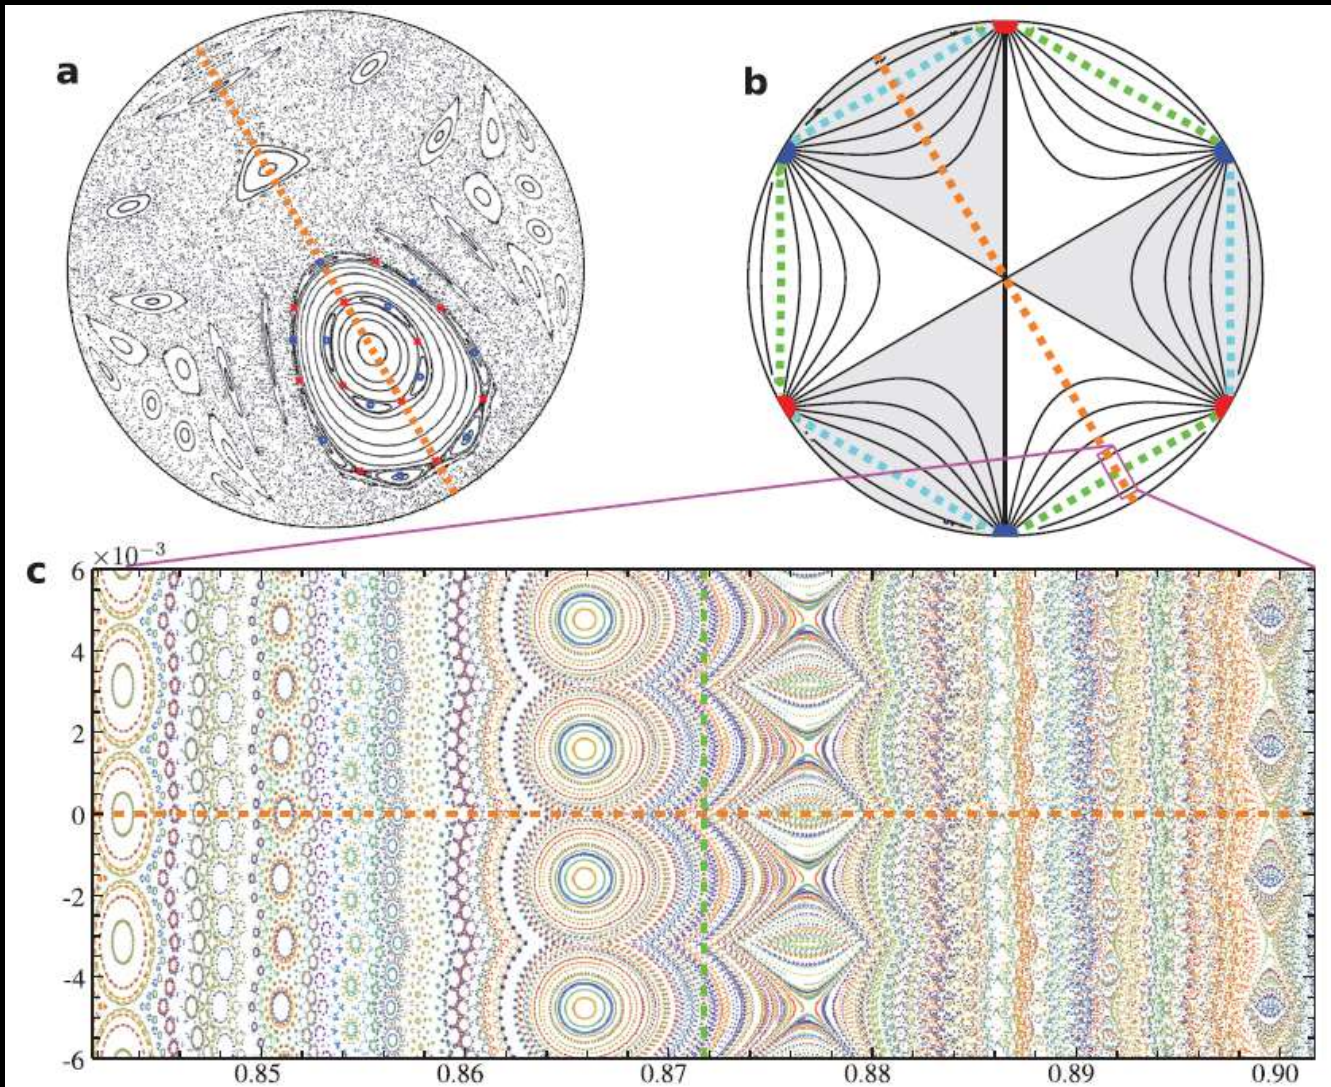

Fluid cutting produced by the dipole

Fluid cutting produced by the dipole

Non-Hamiltonian structures

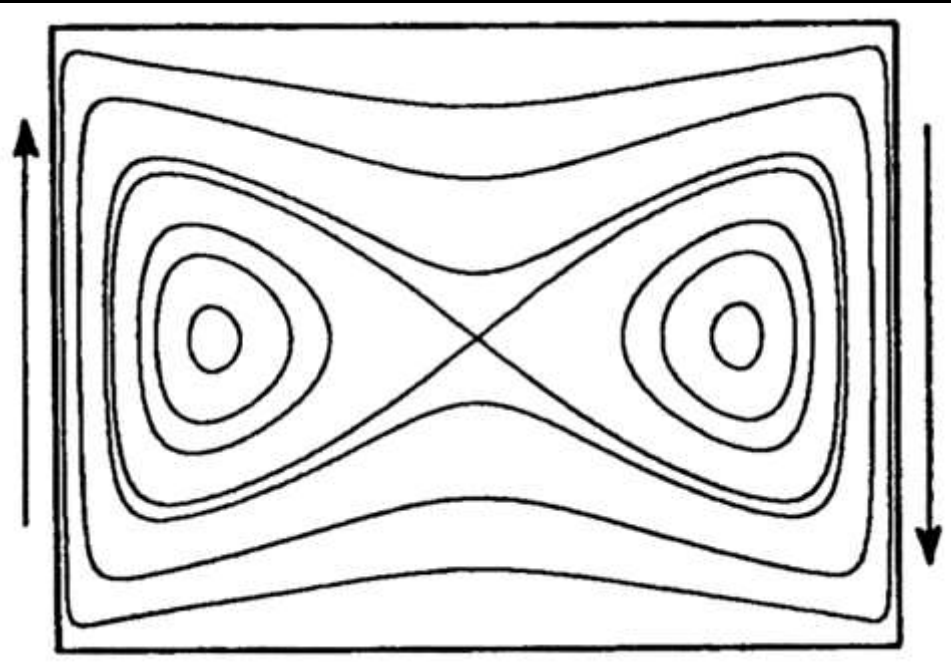

Dynamical Systems Theory: invariant sets, manifolds

Elliptic point

Hyperbolic point

Simple flow

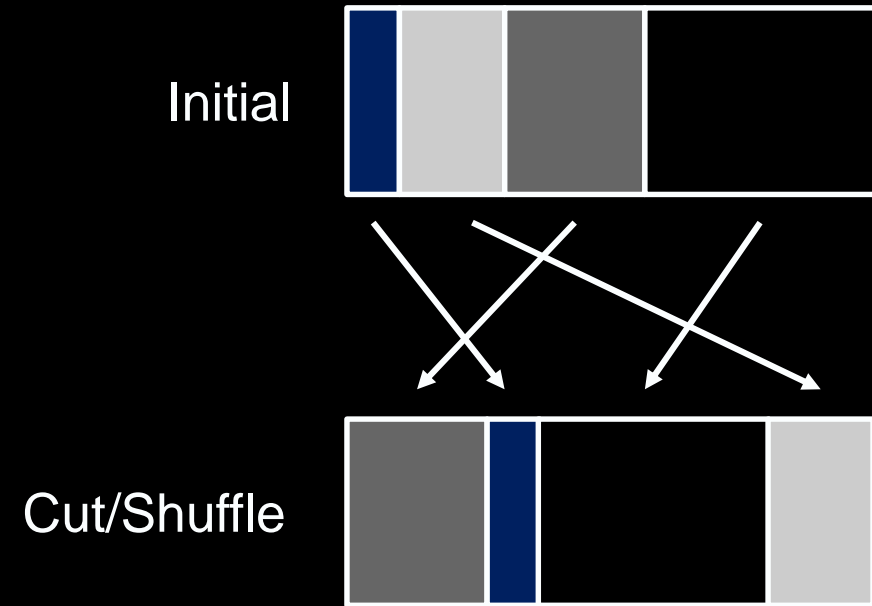

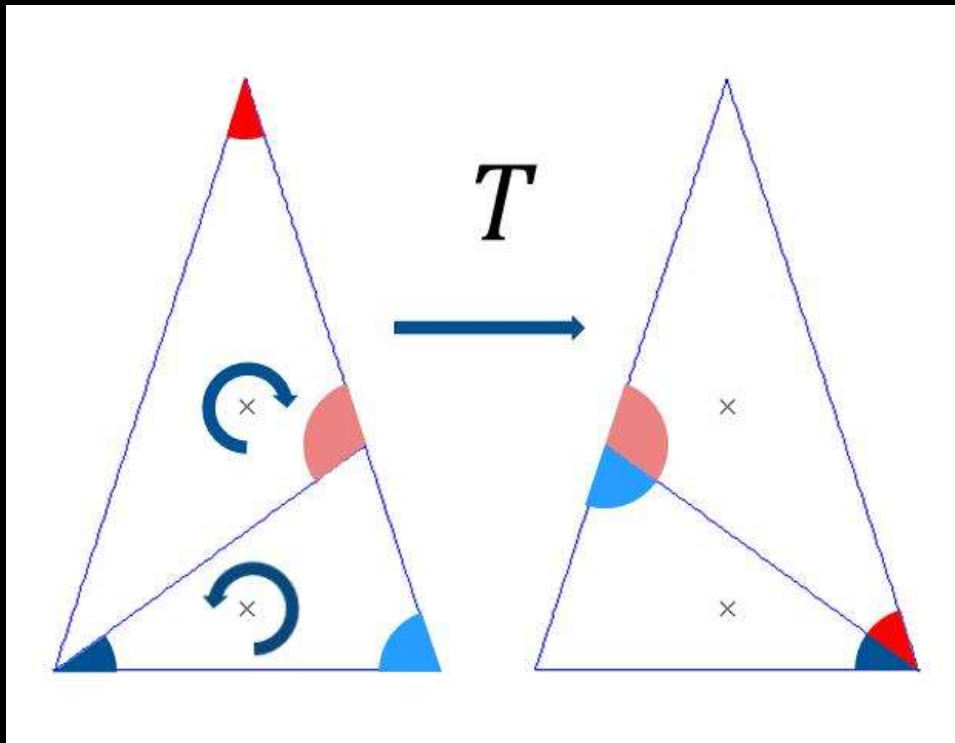

Complex trajectories

Non-Hamiltonian structures

Piecewise Isometry

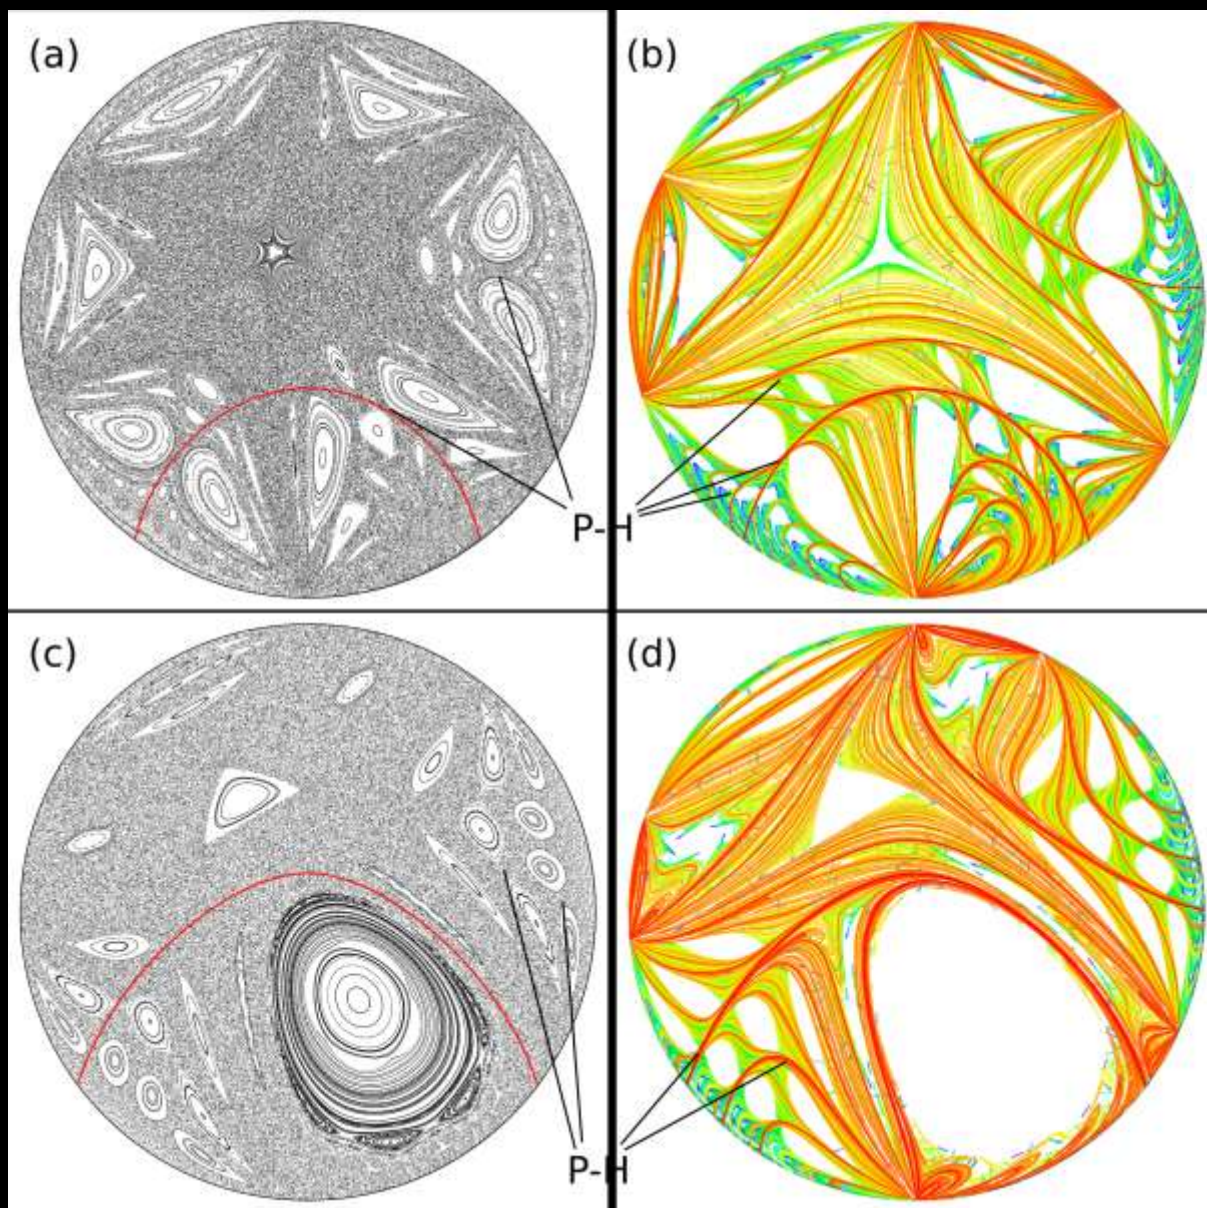

break object into finite pieces, rearrange into original shape

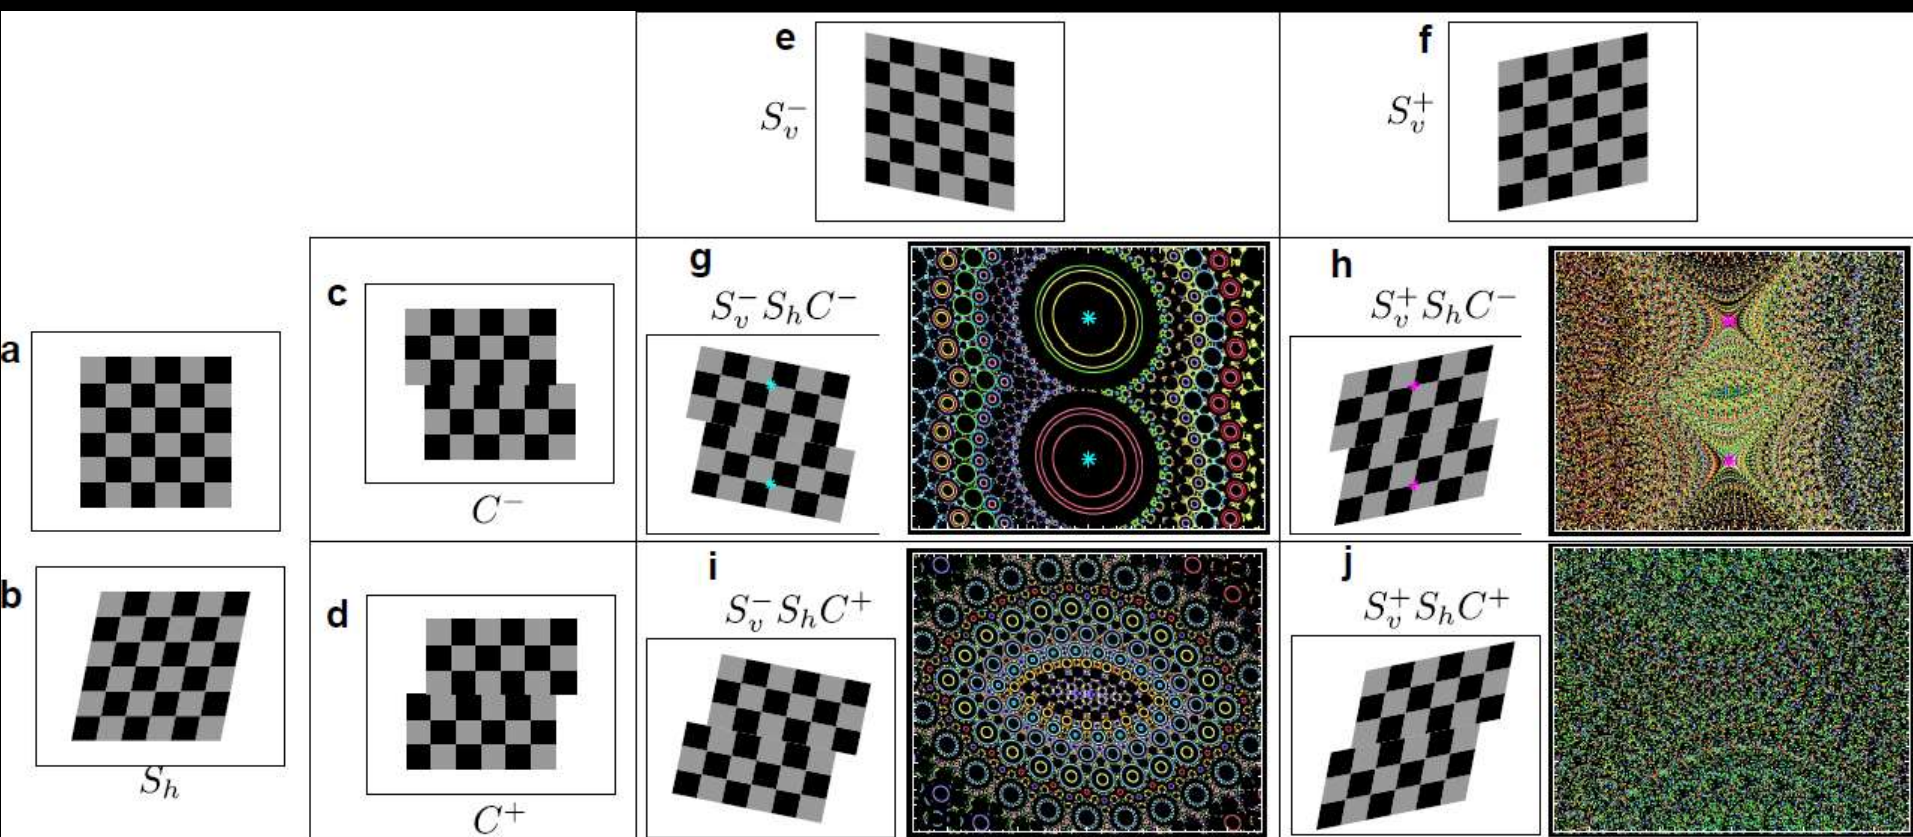

PWI and Exceptional Set (E)

The exceptional set of all images of the cut; physically, it keeps track of where the material has been split

The Cut-Shear-Shear Map

Key Results

Non-Hamiltonian particle transport even though the base flow is Hamiltonian

The “webs of images and preimages” form a kinematic template, similar to that of periodic points, but also includes transport structures created by discontinuous deformations.

Cutting replaces folding

Discontinuous deformations can either enhance or impede mixing

The 3D RPM Flow

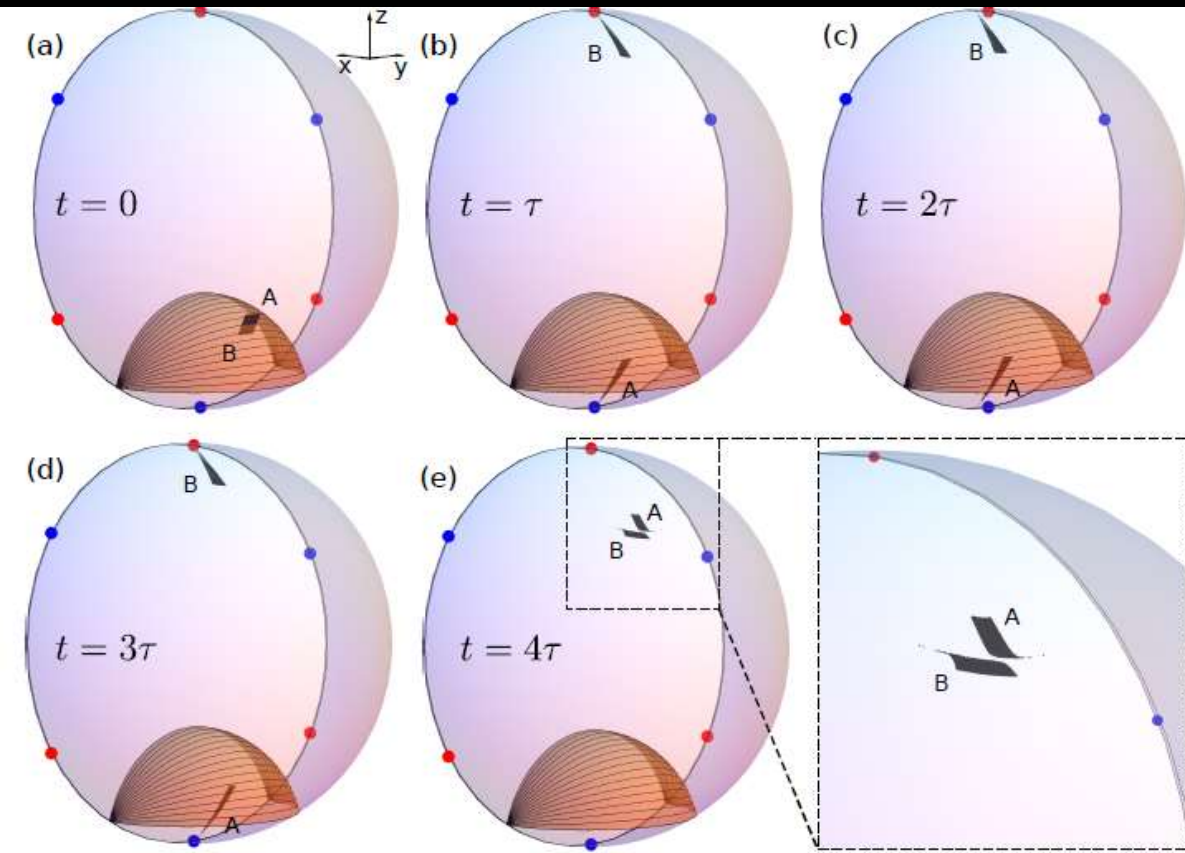

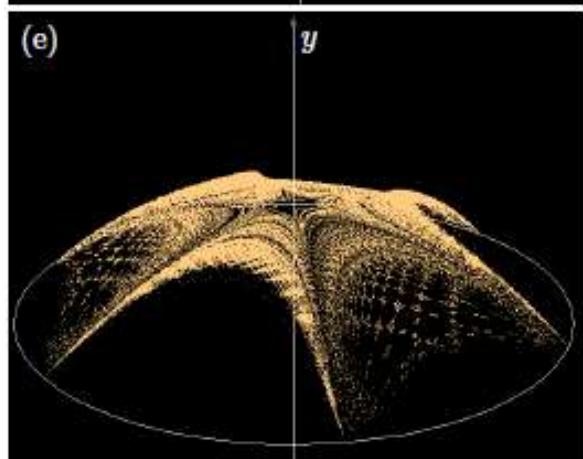

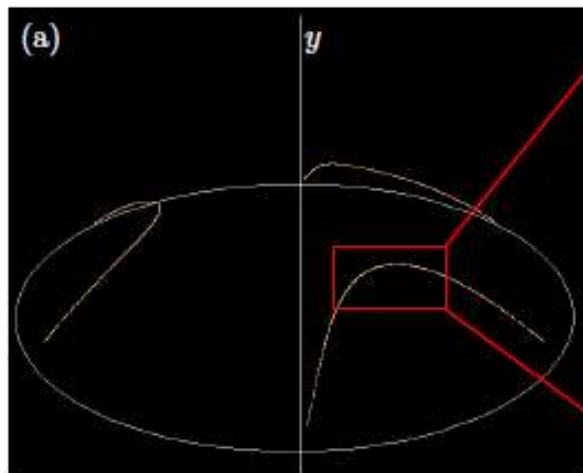

Dipole locations

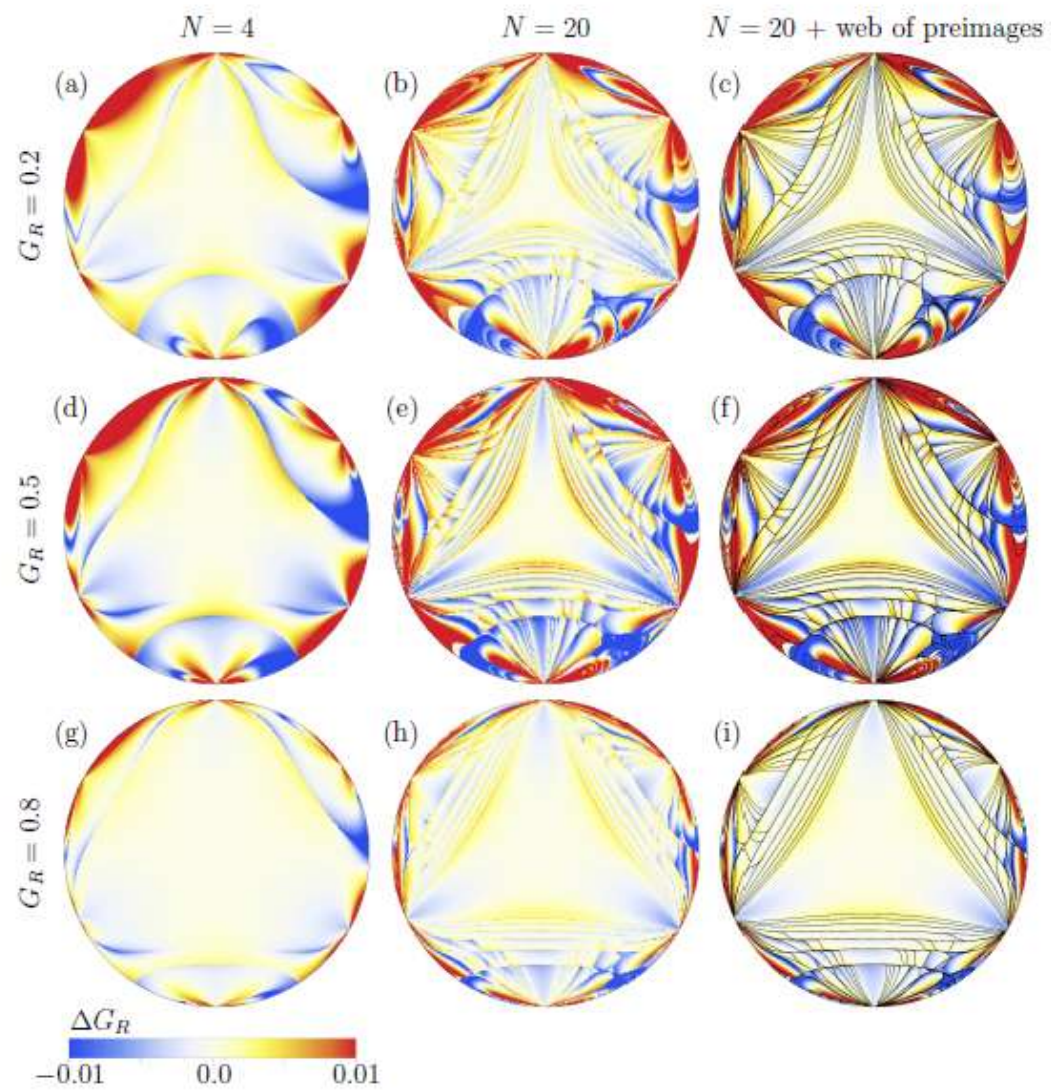

Typical particle trajectory

What can generate in the 3DRPM?
